Notes

A secret manner of writing, ... Generally, the art of writing or solving ciphers.

- Oxford English Dictionary

The analysis and decryption of encrypted text or information without prior knowledge of the keys.

- Oxford English Dictionary

**1967** D. Kahn, *Codebreakers* p. xvi, Cryptology is the science that embraces cryptography and cryptanalysis, but the term 'cryptology' sometimes loosely designates the entire dual field of both rendering signals secure and extracting information from them.

- Oxford English Dictionary

## Cryptography ≠ Security

Cryptography may be a component of a secure system

Just adding cryptography may not make a system secure

## Cryptography: what is it good for?

### Confidentiality

- Others cannot read contents of the message

#### Authentication

- Determine origin of message

### Integrity

- Verify that message has not been modified

#### Nonrepudiation

- Sender should not be able to falsely deny that a message was sent

## Terms

#### Plaintext (cleartext) message P

Encryption *E*(P)

Produces Ciphertext, C = E(P)

**Decryption**, P = D(C)

Cipher = cryptographic algorithm

#### Cryptosystem

Encryption & decryption algorithms for a specific cipher

## Terms

#### Cryptosystem: Encryption & decryption algorithms for a specific cipher

## **Obfuscation and Secret Algorithms**

#### Obfuscation

- The algorithm takes plaintext as input and creates ciphertext
- All security rests in the algorithm
- Vulnerable to leaking and reverse engineering
- Useless once exposed

#### Secret (proprietary) algorithms

No large-scale peer review to validate its effectiveness (who will test it?)

## Many proprietary algorithms have been reverse-engineered and found to be weak

- A5/1, A5/2 used in GSM encryption
- RC3, RC4 used in SSL, WEP (Wired Equivalent Privacy) on Wi-Fi networks
- Crypto AG a Swiss company that added backdoors under direction of the CIA and German BND
- DECT Standard Cipher (DSC) used in cordless phones
- Content Scrambling System (CSS) DVD encryption
- HDCP (High-Bandwidth Digital Content Protection) HDTV interface
- Advanced Access Content System Blu-ray encryption
- Firewire protocol
- Enigma cipher machine German WWII cipher
- Every NATO and Warsaw Pact algorithm during Cold War

"Anyone, from the most clueless amateur to the best cryptographer, can create an algorithm that he himself can't break. It's not even hard."

### - Bruce Schneier

See https://en.wikipedia.org/wiki/Category:Broken cryptography algorithms

## Shared algorithms & secret keys

## The key

BTW, the above is a *bump key*. See http://en.wikipedia.org/wiki/Lock\_bumping

## The lock

Source: en.wikipedia.org/wiki/Pin\_tumbler\_lock

## The key & lock

- We understand how the mechanism works:
  - Strengths
  - Weaknesses
- Based on this understanding, we can assess how much to trust the key & lock

Source: en.wikipedia.org/wiki/Pin\_tumbler\_lock

# A cryptosystem should be secure even if everything about the system, except the key, is public knowledge

#### Security should rest entirely on the secrecy of the key

#### One shared secret key, K, for encryption & decryption

 $C = E_{\mathcal{K}}(\mathsf{P})$  $\mathsf{P} = D_{\mathcal{K}}(\mathsf{C})$ 

## Classic Cryptosystems: Substitution Ciphers

## Atbash (אתבש) – Ancient Hebrew cipher

No information (key) needs to be conveyed!

## India – Mlecchita vikalpa: Kautiliya

"The art of understanding writing in cypher, and the writing of words in a peculiar way"

### Kautiliya

- Documented in the Kama Sutra
- Phonetic substitution scheme used in India 400 BCE 200 CE
- Short & long vowels are exchanged with consonants

kh	g	gh	'n	ch	j	jh	ñ	ţh	ģ	dh	ņ	th	d	dh	n	ph	b	bh	m	У	r	I	v

## Cæsar cipher

#### Earliest documented military use of cryptography

- Julius Caesar c. 60 BCE
  - Documented by the Roman historian Suetonius in De Vita Caesarum
- Shift cipher: a simple form of a substitution cipher
- Each letter is replaced by one *n* positions away modulo alphabet size
  - n =shift value =key

Caesar used n = 3

# A B C D E F G H I J K L M N O P Q R S T U V W X Y Z A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

# A B C D E F G H I J K L M N O P Q R S T U V W X Y Z U V W X Y Z A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

 $\rightarrow$  shift alphabet by n (6)

## Cæsar cipher

#### **MY CAT HAS FLEAS**

ds

## Cæsar cipher

#### **MY CAT HAS FLEAS**

- One piece of information is needed for decryption: key = shift value
- Trivially easy to crack (25 possibilities for a 26-character alphabet)

## Monoalphabetic substitution cipher

Monoalphabetic = constant mapping between plaintext and ciphertext

General case: arbitrary mapping

(versus a Cæsar cipher, where the letters are in an alphabetic sequence but shifted)

Both sides must have the same substitution alphabet

#### Easy to decode: vulnerable to frequency analysis

	by Dick 2M chars)		akespeare .8M chars)	Common digrams
e o	12.300% 7.282%	e o	11.797% 8.299%	TH (3.56%), HE (3.07%), IN (2.43%), ER (2.05%), AN, RE,
d b	4.015% 1.773%	d b	3.943% 1.634%	Common trigrams
X	0.108%	X	0.140%	THE, ING, AND, HER, ERE

## Shannon Entropy

Shannon Entropy is a measure of the uncertainty or randomness in a set of data

$$H(X) = -\sum P(x) \log_2 P(x)$$

where P(x) is the probability of occurrence of a particular outcome x (e.g., the frequency of a character appearing in the message)

#### It measures the amount of information in bits

High entropy = more randomness  $\Rightarrow$  which is what we want for ciphertext

CS 419 © 2025 Paul Krzyzanowski

## Entropy

If all letters were equally probable in a message, the entropy would be  $log_2 26 = 4.70$  bits of information per byte

- Moby Dick text: entropy = 4.175
- Shakespeare texts: entropy = 4.19

## Monoalphabetic substitution ciphers don't increase entropy

The frequency of characters remains the same – they're just different characters

Increase entropy by enabling the same character to be encrypted differently in different parts of the message

If each letter's probability is the same:

$$H = -\sum_{i=1}^{26} \frac{1}{26} \log_2\left(\frac{1}{26}\right)$$
$$H = -26 \times \frac{1}{26} \log_2\left(\frac{1}{26}\right)$$

$$H = -\log_2\left(\frac{1}{26}\right)$$

 $H = \log_2(26)$ 

H = 4.7004

## Polyalphabetic substitution ciphers

### Designed to thwart frequency analysis techniques

- Different ciphertext symbols can represent the same plaintext symbol  $1 \rightarrow many$  relationship between letter and substitution

#### Leon Battista Alberti: 1466

- Two disks
- Line up predetermined letter on inner disk with outer disk
- Plaintext on inner  $\rightarrow$  ciphertext on outer
- After *n* symbols, the disk is rotated to a new alignment

## Vigenère polyalphabetic cipher

#### Blaise de Vigenère, court of Henry III of France, 1518

No need for a disk: use table and key word to encipher a message

"The rebels reposed their major trust, however, in the Vigenère, sometimes using it in the form of a brass cipher disc. In theory, it was an excellent choice, for so far as the South knew the cipher was unbreakable. In practice, it proved a dismal failure. For one thing, transmission errors that added or subtracted a letter ... unmeshed the key from the cipher and caused no end of difficulty. Once Major Cunningham of General Kirby-Smith's staff tried for twelve hours to decipher a garbled message; he finally gave up in disgust and galloped around the Union flank to the sender to find out what it said."

# Cryptanalysis of the Vigenère cipher

It was hard to break with long keys and small amounts of ciphertext

## Cryptanalysis of the Vigenère cipher

## **1.** Determine key length

- Count coincidences identical sets of characters *n* characters apart
- Key length is likely to be the separation with the maximum # of coincidences
  - Compare likelihood of letter repetition in ciphertext to that of randomly distributed text

## 2. Determine values of each character of the key

- You know the length of the key that's the # of Caesar ciphers you have
- Do a frequency analysis of each position of the key

# Vernam Cipher (1917): One-time pad

We can achieve maximum entropy by using a truly random key that is as long as the message

- Large non-repeating set of *random* key letters originally written on a pad
- Each key letter on the pad encrypts exactly one plaintext character

- Encryption is addition of characters modulo *alphabet size* (e.g., 26)
- Sender destroys pad pages that have been used
- Receiver maintains an identical pad to decrypt the message

# Digression: exclusive-or

# Boolean logic refresher: AND

## AND (^): clears bits

## AND clears bits

- AND 1 keep the bit
- AND 0 clear the bit

Truth table  $1 \land 1 = 1$   $1 \land 0 = 0$   $0 \land 1 = 0$   $0 \land 0 = 0$ 

## If you clear a bit, you will never know if it used to be a 0 or a 1

Note: I'm using Boolean algebra notation here. The BCPL and B languages used & and I for AND and OR, respectively – for both logical (conditional) and bitwise operations. C, the successor to B, introduced the use of ^ for a bitwise XOR operation and && and II for logical AND and OR operations. C++, C#, D, Java, Perl, Ruby, PHP and Python followed the convention of using ^ as an exclusive-or operator.

# Boolean logic refresher: OR

# OR (V): sets bits

## OR sets bits

- OR 1 set the bit
- OR 0 keep the bit

Truth table  $1 \lor 1 = 1$   $1 \lor 0 = 1$   $0 \lor 1 = 1$  $0 \lor 0 = 0$ 

## If you set a bit, you will never know if it used to be a 0 or a 1

# Boolean logic refresher: Exclusive-OR (XOR)

## XOR ( $\oplus$ ): flips bits

## **XOR flips bits**

- XOR 1 flip the bit
- XOR 0 keep the bit as it is

Truth table  $1 \bigoplus 1 = 0$   $1 \bigoplus 0 = 1$   $0 \bigoplus 1 = 1$   $0 \bigoplus 0 = 1$ 

## If you flip a bit, you can restore it by XORing it with 1 again

## We use XOR operations a lot in cryptography

They allow us to flip certain bits to encrypt and later unflip to decrypt

# One-time pads provide **perfect secrecy**

## **Perfect secrecy**

- Ciphertext conveys no information about the content of plaintext
- Achieved only if the key is random and as long as the plaintext

## Problems with one-time pads:

- The key needs to be as long as the message!
- Key storage and distribution can be problematic
- Keys must be generated randomly
  - Cannot use a pseudo-random number generator
- Cannot reuse key sequence
- Sender and receiver *must* remain synchronized (e.g., cannot lose any part of the message)

# Reusing a key with a one-time pad

We're using a one-time pad to encrypt two image files using a random key as long as the message. But the same key was used for the two images.

# Random numbers

"Anyone who considers arithmetical methods of producing random digits is, of course, in a state of sin"

– John von Neumann, 1951

#### Pseudo-random generators

- Linear feedback shift registers
- Multiplicative lagged Fibonacci generators
- Linear congruential generator

#### Obtain randomness from:

- Time between keystrokes
- Various network/kernel events
- Cosmic rays
- Electrical noise, thermal noise
- Other encrypted messages

# Researchers use tiny magnetic swirls **PHYS** to generate true random numbers

by Brown University February 7, 2022

Whether for use in cybersecurity, gaming or scientific simulation, the world needs true random numbers, but generating them is harder than one might think. But a group of Brown University physicists has developed a technique that can potentially generate millions of random digits per second by harnessing the behavior of skyrmions—tiny magnetic anomalies that arise in certain two-dimensional materials.

Their research, published in Nature Communications, reveals previously unexplored dynamics of single skyrmions, the researchers say. Discovered around a half-decade ago, skyrmions have sparked interest in physics as a path toward next-generation computing devices that take advantage of the magnetic properties of particles—a field known as spintronics.

# New quantum random number generator achieves 2 Gbit/s speed

by Ingrid Fadelli June 11, 2024

The reliable generation of random numbers has become a central component of information and communications technology. In fact, random number generators, algorithms or devices that can produce random sequences of numbers, are now helping to secure communications between different devices, produce statistical samples, and for various other applications.

Researchers at Toshiba Europe Ltd. recently developed a new quantum random number generator (QRNG) based on a photonic integrated circuit that can be directly integrated in electronic devices. This QRNG, introduced in a paper published in *Nature Electronics*, can securely and robustly generate random numbers at a remarkable speed of 2 Gbit s<sup>-1</sup>.

# **Rotor machines**

## 1920s: mechanical devices used for automating encryption

## **Rotor machine:**

- Set of independently rotating cylinders (rotors) through which electrical pulses flow
- Each rotor has input & output pin for each letter of the alphabet
  - Each rotor implements a substitution cipher
- Output of each rotor is fed into the next rotor
- Together they implement a version of the Vigenère cipher (with a long period)

# The rotor in a rotor machine

# **Rotor machines**

After a character is entered, the cylinder rotates one position

- Internal connections shifted by one
- Polyalphabetic substitution cipher with a period of 26

# Single cylinder rotor machine

# Multi-cylinder rotor machines

## Single cylinder rotor machine

- Substitution cipher with a period = length of the alphabet (e.g., 26)

## Multi-cylinder rotor machine

- Feed output of one cylinder as input to the next one
- First rotor advances after the character is entered
- The second rotor advances after a full period of the first
- Polyalphabetic substitution cipher

## Period = (length of alphabet)<sup>number of rotors</sup>

- 3 26-char cylinders  $\Rightarrow$  26<sup>3</sup> = 17,576 substitution alphabets
- 5 26-char cylinders  $\Rightarrow$  26<sup>5</sup> = 11,881,367 substitution alphabets

# Enigma

- Enigma machine used in Germany during WWII
- Three rotor system
  - $26^3 = 17,576$  possible rotor positions
- Input data permuted via patch panel before sending to rotor engine
- Data from last rotor reflected back through rotors ⇒ makes encryption symmetric
- All parties agree on the initial settings of the rotors
  - Setting was *f(date)* in a book of codes
- Broken by Marian Rejewski of the Polish Cipher Bureau
  - Alan Turing at Bletchley Park designed the British bombe device to identify the rotor order

See https://en.wikipedia.org/wiki/Cryptanalysis\_of\_the\_Enigma

# Enigma

# Enigma successor: Soviet Union's Fialka

The Soviet Union needed a more secure cipher than Enigma

- Rotor machine with 10 rotors and 30 contacts/rotor
  - Fialka:  $30^{10} = 5.9 \times 10^{14}$  possible rotor positions
  - Enigma:  $26^3 = 17,576$  possible rotor positions
- Punched cards configure initial settings
- More complex stepping mechanism than Enigma
- Various versions used by Warsaw Pact countries into the 1990s

## Soviet Union Fialka – 10-rotor system

# Classic Cryptosystems: Transposition Ciphers
## Transposition ciphers

- Permute letters in plaintext according to specific rules
- Knowledge of rules will allow messages to be decrypted
- First documented use by Spartans in the 5<sup>th</sup> century BCE
  - **Scytale** (*rhymes with Italy*) = staff cipher

### **Transposition ciphers:**

- Scramble the letters of the plaintext
- Split common letter sequences to increase the entropy of digraphs and trigraphs

Secret = diameter of scytale

**Padding:** adding extra data to the plaintext to ensure that its length is a multiple of a specific block size

- Enter data horizontally, read it vertically
- Secrecy is the width of the table

- Created in the mid 1600s used by the French, Japanese, & Russians into the 20<sup>th</sup> century
- Key word defines the width of the table and the sequence of reading the columns
- Read down columns, sorting by key letters

- Shuffle columns based on the sorting of letters in the key word

- Read down columns

## Transposition cipher

- Not vulnerable to frequency analysis
- Entropy of characters does not change
  - But the entropy of digraphs and trigraphs increases because common sequences are broken through scrambling the characters

### The scytale is trivial to attack

- Make all possible matrices that would fit the ciphertext
- Write ciphertext across rows
- See if the columns contain legible content

### Scrambled columns make it a bit harder

- Need to permute columns of matrices

## Combined ciphers

- Combine transposition with substitution ciphers
  - German ADFGVX cipher (1918, World War I)
  - Playfair cipher (Charles Wheatstone, 1854)
- Great for increasing entropy of characters, digraphs, trigraphs, ...
- But was troublesome to implement (before computers)
  - Difficult with pencil-and-paper or electromechanical cryptography
  - Except for the simplest ciphers, requires memory to store blocks of data for transposition

# Properties of a good cryptosystem

## Kerckhoffs's Principle of Cryptography

### Kerckhoffs's Principle - 1883

A cryptosystem should be secure even if everything about the system, except the key, is public knowledge

In other words ...

"One ought to design systems under the assumption that the enemy will immediately gain full familiarity with them." - Claude Shannon, 1949

What this means:

If you don't know the key, you will have to do an exhaustive search (try all combinations). The amount of effort to decrypt data without knowing the key is proportional to the length of the key

## Properties of a good cryptosystem (1)

- 1. Ciphertext should be indistinguishable from random values
  - Ciphertext should have high entropy: no patterns and no data that can give the attacker a clue of what any parts of the key or the plaintext could be
- 2. Kerckhoffs's Principle: The secrecy should reside in the key, not the algorithm
  - The algorithm should be public so it could be analyzed
- 3. There should be no way to extract the original plaintext or the key short of enumerating all possible keys (i.e., a brute-force attack)
  - **Non-invertible**: the ciphertext cannot be decrypted without the key
  - This is true even if the attacker has many (P, C) pairs or can supply an arbitrary amount of plaintext to be encrypted and see the resulting ciphertext

## Properties of a good cryptosystem (2)

#### 4. The keys should be large enough that an exhaustive search is not feasible

- Because all secrecy is in the key, we need a key large enough that testing all values is not possible in a reasonable amount of time (even on a network of the fastest computers we expect to have 20 years from now).
- A cipher is no stronger than its key length
  - If the key is too short, an attacker a brute-force search may be feasible
  - A cipher may be a lot weaker than its key length

#### 5. The cipher should not contain weak keys

- There should be no keys that result in weaker security

## Additional properties of a good cryptosystem

#### 6. Encryption and decryption should be efficient

- We want to encourage the use of secure cryptography where it is needed and not have people avoid it because it slows down data access

#### 7. Keys and algorithms should be as simple as possible and operate on any data

- There shouldn't be restrictions on the values of keys, the data that could be encrypted, or how to do the encryption
- Restrictions on keys make searches easier and will require longer keys.
- Complex algorithms will increase the likelihood of implementation errors
- Restrictions on what can be encrypted will encourage people to not use the algorithm

#### 8. The size of the ciphertext should be the same size as the plaintext

- You don't want your effective bandwidth cut in half because the ciphertext is 2x the size of plaintext
- Sometimes we might need to pad the data or add a header but that's a fixed number of bytes regardless of the input size

#### 9. The algorithm has been extensively analyzed

- We want an algorithm that has been studied carefully for years by many experts

## About keys

### Keys should be

#### Protected

If attackers get hold of the keys, they can decrypt ciphertext

### Random Keys should be unpredictable

### Short term (ideally): Used for a limited time

Less (P,C) data gives cryptanalysts less data to analyze

## Keys and the power of 2

- Each extra bit added to a key doubles the search space
- Suppose it takes 1 millisecond to search through all keys with a 20-bit key

key length	number of keys	search time*	10,000 computers
20 bits	1,048,576	0.001 seconds	0.0000001 seconds
21 bits	2,097,152	0.002 seconds	0.0000002 seconds
32 bits	4.3 × 10 <sup>9</sup>	4.1 seconds	.0004 seconds
56 bits	7.2 × 10 <sup>16</sup>	2.2 years	2 hours
64 bits	1.8 × 10 <sup>19</sup>	557 years	20 days
128 bits	3.4 × 10 <sup>29</sup>	1.03 × 1022 years	1.03 × 1018 years
256 bits	1.2 × 1077	1.1 × 1067 years	1.1 × 1064 years

The universe is estimated to be  $1.3 \times 10^{10}$  years old

\*Assume the computer can test 1 billion keys per second

## Shannon's Properties: Confusion and Diffusion

### Claude Shannon defined two operational goals of a cipher:

### Confusion

- There is no direct correlation between a bit of the key and the resulting ciphertext
- Every bit of ciphertext depends on various bits of the key. You cannot find a connection between a bit of the key and a bit of the ciphertext.
- Generally implemented through substitution
- Confusion hides the relationship between the key and ciphertext

### Diffusion

- The plaintext information is **spread** throughout the cipher so that a change in one bit of plaintext will change, on average, half of the bits in the ciphertext will change.
- Generally implemented through transposition
- Diffusion tries to make the relationship between the plaintext and ciphertext as complicated as possible

# Computer Cryptography

### Properties

- Operate on arbitrary binary data: P = {0, 1}<sup>n</sup>
- Kerckhoffs's Principle: the secrecy resides in the key
- Shannon's properties
  - Confusion: no direct correlation between a bit of the key and the resulting ciphertext
  - Diffusion: Changing one bit of input should change, on average, ½ of output bits

### Main mechanisms

1011		<b>↓ 1011</b>	, 1011 ,	
S-box	Substitute one sequence of bits into a different sequence (non-linear transformation)	P-box	Transposition (permutation): Shuffle bits between the input and output ⇒ provide diffusion	
0010	$\Rightarrow$ provide confusion	1110		

## **Block ciphers**

### Block ciphers dominate computer cryptography

Encrypt a fixed number of bits (a *block*) at a time Output blocksize (usually) == input blocksize

## Block ciphers

- Block ciphers encrypt a <u>block</u> of plaintext at a time
- DES & AES are two popular block ciphers
  - DES: 64-bit blocks
  - AES: 128-bit blocks
- Block ciphers are usually iterative ciphers
  - The encryption process is an iteration through several *round* operations
  - A single round does not provide perfect confusion or diffusion

### Structure of block ciphers

- Multiple rounds of combining the plaintext with the key
- Optional:
  - Convert key to an internal subkey different for each round
- DES: 16 rounds
- AES: 10-14 rounds, depending on key length

Sounds easy ... but is difficult to design

## Block cipher rounds

#### Each round consists of substitutions & permutations = **SP Network**

#### Substitution = **S-box**

- Table lookup
- Converts a small block of input to a block of output

#### **Permutation**

- Scrambles the bits in a prescribed order

#### Key application per round

- Subkey,  $K_n$ , per round derived from the key
- Can drive behavior of s-boxes
- May be XORed with the output of each round

#### Create Confusion & Diffusion

- Confusion: no direct correlation between a bit of the key and resulting ciphertext
- Diffusion: Changing one bit of input should change, on average, ½ of output bits

### **Data Encryption Standard**

- Developed in the early 1970s by IBM and modified by the NSA
- Adopted as a federal standard in 1976

- Block cipher, 64-bit blocks, 56-bit key
- Substitution followed by a permutation
  - Transposition and XORs based on a subkey derived from the key
  - 16 rounds

## Feistel cipher

• DES is a type of Feistel cipher, which is a form of a block cipher

### Plaintext block is split in two

- Round function applied to one half of the block
- Output of the round function is XORed with the other half of the block
- Halves are swapped
- This is a Feistel Network rather than an SP Network

DES

# DES: f per round

## **DES:** S-boxes

#### After compressed key is XORed with expanded block

- 48-bit result moves to substitution operation via eight substitution boxes (s-boxes)
- Each S-box has
  - 6-bit input
  - 4-bit output

S-boxes are used in symmetric block ciphers to add <u>confusion</u>: hide the relationship of any ciphertext from any plaintext & key bits.

48 bits divided into eight 6-bit sub-blocks

- Each block is operated by a separate S-box
- Net result: 48-bit input generates 32-bit output
- S-boxes are key components of DES's security

Implemented as a table lookup

## Is DES secure?

#### 56-bit key makes DES relatively weak

- $2^{56} = 7.2 \times 10^{16}$  keys
- Brute-force attacks possible
- By the late 1990's:
  - DES cracker machines built to crack DES keys in a few hours
  - DES Deep Crack: 90 billion keys/second
  - Distributed.net: tested 250 billion keys/second

### 2000s < 1 day</li>

- 2006: COPACOBANA: Custom FPGA-based DES cracker for < \$10,000
- 2012: cloud-based service crack MS-CHAPv2 authentication (which uses DES) on sale for \$20

https://boingboing.net/2012/09/24/exhaust-all-of-des-and-crack-a.html

## Increasing The Key Size

### Could double encryption work for DES?

Useless if we could find a key K such that:

$$\mathsf{E}_{\mathsf{K}}(\mathsf{P}) = \mathsf{E}_{\mathsf{K}2}(\mathsf{E}_{\mathsf{K}1}(\mathsf{P}))$$

This does not hold for DES (luckily!)

## Double DES

### Vulnerable to *meet-in-the-middle* attack

### If we know some pair (P, C), then:

[1] Encrypt *P* for all 2<sup>56</sup> values of *K*<sub>1</sub>
[2] Decrypt *C* for all 2<sup>56</sup> values of *K*<sub>2</sub>

### For each match where [1] == [2]

- Test the two keys against another P, C pair
- If match, you are assured that you have the key
- The complexity is  $2 \times 2^{56}$  rather than  $2^{2 \times 56}$

# Triple DES key lengths

Triple DES with two 56-bit keys (112-bit key):

 $\mathsf{C} = \mathsf{E}_{\mathsf{K1}}(\mathsf{D}_{\mathsf{K2}}(\mathsf{E}_{\mathsf{K1}}(\mathsf{P})))$ 

Triple DES with three 56-bit keys (168-bit key):

 $\mathbf{C} = \mathbf{E}_{\mathrm{K3}}(\mathbf{D}_{\mathrm{K2}}(\mathbf{E}_{\mathrm{K1}}(\mathbf{P})))$ 

Decryption used in middle step for compatibility with DES ( $K_1 = K_2 = K_3$ )

$$C = E_{K}(D_{K}(E_{K}(P))) \equiv C = E_{K1}(P)$$

## **DES** Disadvantages

- DES has been shown to have some weaknesses
  - Key can be recovered using 2<sup>47</sup> chosen plaintexts or 2<sup>43</sup> known plaintexts
  - Note that this is not a practical amount of data to get for a real attack!
- Short block size (8 bytes =  $2^8 = 64$  bits)
- The biggest weakness of DES is its 56-bit key
  - Exhaustive search requires 2<sup>55</sup> iterations on average

#### • 3DES solves the key size problem: we can have keys up to 168 bits

- Differential & linear cryptanalysis is not effective here: the three layers of encryption use 48 rounds instead of 16 making it infeasible to reconstruct s-box activity
- But DES is relatively slow and 3DES is 3x slower
  - It was designed with hardware encryption in mind: and 3DES is 3x slower than DES

# AES (Advanced Encryption Standard)

### • U.S. NIST held a competition for a new algorithm

- Received 15 submissions
- No NSA tampering allowed
- Three variations (key lengths) of the Rijndael family of ciphers won

### Block cipher: 128-bit blocks

- AES is *not* a Feistel cipher it uses the entire block in each round
- DES used 64-bit blocks but encrypted half the data in each round

### Successor to DES as a standard encryption algorithm

- DES: 56-bit key
- AES: 128, 192, or 256-bit keys

### From NIST:

Assuming that one could build a machine that could recover a DES key in a second (i.e., try 2<sup>56</sup> keys per second), then it would take that machine approximately 149 trillion years to crack a 128-bit AES key. To put that into perspective, the universe is believed to be less than 20 billion years old.

https://www.nist.gov/news-events/news/2001/12/commerce-secretary-announces-new-standard-global-information-security

# AES (Advanced Encryption Standard)

### • Iterative cipher, just like most other block ciphers

- Each round is a set of substitutions & permutations

### Variable number of rounds

- DES always used 16 rounds
- AES:
  - 10 rounds: 128-bit key
  - 12 rounds: 192-bit key
  - 14 rounds: 256-bit key
- A subkey ("round key") derived from the key is computed for each round
  - DES used this too, as do all multi-round ciphers

## Each AES Round

#### Step 1: Byte Substitution (s-boxes)

- Substitute 16 input bytes by looking each one up in a table (s-box)
- Result is a 4x4 matrix

#### Step 2: Shift rows

- Each row is shifted to the left (wrapping around to the right)
- 1<sup>st</sup> row not shifted; 2<sup>nd</sup> row shifted 1 position to the left;
   3<sup>rd</sup> row shifted 2 positions; 4<sup>th</sup> row shifted three positions

#### Step 3: Mix columns

- 4 bytes in each column are transformed
- This creates a new 4x4 matrix
- Step 4: XOR round key
  - XOR the 128 bits of the round key with the 16 bytes of the matrix in step 3

## **AES** Decryption

### Same rounds ... but in reverse order

## **AES** Advantages

- Larger block size: 128 bits vs 64 bits
- Larger & varying key sizes: 128, 192, and 256 bits
  - 128 bits is complex enough to prevent brute-force searches
- No significant academic attacks beyond brute force search
  - Resistant against linear cryptanalysis thanks to bigger S-boxes
    - S-box = lookup table that adds non-linearity to a set of bits via transposition & flipping
  - DES: 6-bit inputs & 4-bit outputs
  - AES: 8-bit inputs & 8-bit outputs
- Typically 5-10x faster in software than 3DES

### Attacks against AES

#### Attacks have been found

- This does *not* mean that AES is insecure!

#### • Because of these weaknesses:

- AES-128 has a computational complexity of 2<sup>126.1</sup> (~126 bits)
- AES-192 has a computational complexity of 2<sup>189.7</sup> (~190 bits)
- AES-256 has a computational complexity of 2<sup>254.9</sup> (~255 bits)

#### Increasing AES security

- The security of AES can be increased by increasing the number of rounds in the algorithm
- However, AES-128 still has a sufficient safety margin to make exhaustive search attacks impractical

## Stream ciphers – simulate a one-time pad

#### Keystream generator produces a sequence of pseudo-random bytes

 $C_i = S_i \oplus P_i$ 

Just like with the one-time pad, you can never reuse a key

 $C = A \oplus K$  $C' = B \oplus K$  $C \oplus C' = A \oplus K \oplus B \oplus K = A \oplus B$ 

Guess A to get K and see if B makes sense

Or... if you have **known plaintext** A and the corresponding ciphertext C, you can extract the key:

 $\mathsf{K}=\mathsf{A}\oplus\mathsf{C}$ 

## So how can you use the same key?

- A stream cipher will typically incorporate a unique random value, called an initialization vector (IV) along with the key
- The initialization vector may be public
  - It can be added as a header to the ciphertext
- This ensures the keystream generated will be different even if the same key is used multiple times
